

Figure 1: Number of jobs in each NTA tract. Job count is calculated from the sum of all trips which end in that NTA. It is standardized by the total area of the NTA. It is also transformed with a natural log.

Figure 2: Frequency of commute counts, standardized by the sum of the areas of the commute's origin and destination NTAs

Figure 3: Frequency of the natural log of commute counts, standardized by the sum of the areas of the commute's origin and destination NTAs

Figure 4: Boxplot for the number of commutes, factored by the number of subway lines used during the commute. Commutes are transformed by a natural log and standardized by area

Figure 5: Time in transit on the subway plotted against the number of commutes standardized by area. A smoother line is overlaid in blue.

Figure 6: Time in subway transit is tranformed by raising it to the power of one-eighth and taking the inverse. Commute count is transformed with the natural log. The values are plotted against each other. A smoother line is overlaid in blue.

Figure 7: Diagnostic plots for the model of transformed subway transit time

Figure 8: Time driving in traffic plotted against the number of commutes standardized by area. A smoother line is overlaid in blue.

Figure 9: Time driving in traffic is transformed by raising it to the power of one-eighth and taking the inverse. Commute count is transformed with the natural log. The values are plotted against each other. A smoother line is overlaid in blue.

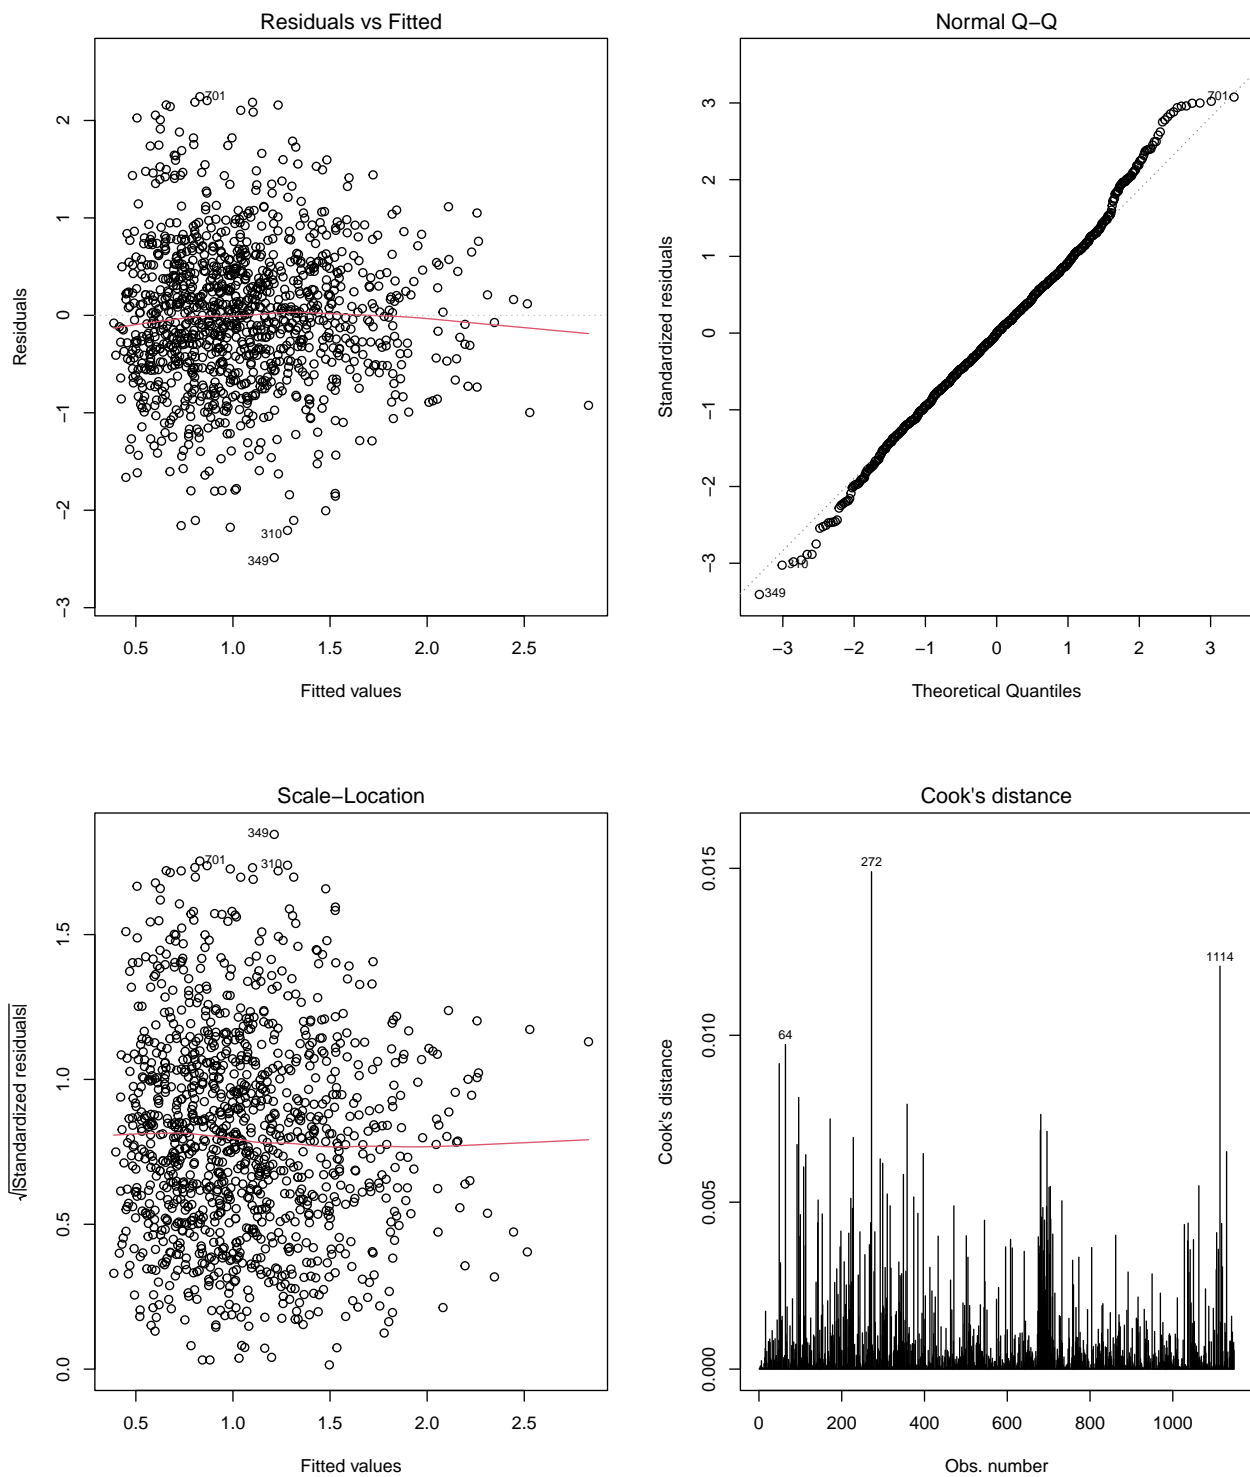

Figure 10: Diagnostic plots for the model of transformed driving time

Figure 11: Time spent walking plotted against the number of commutes standardized by area. A smoother line is overlaid in blue.

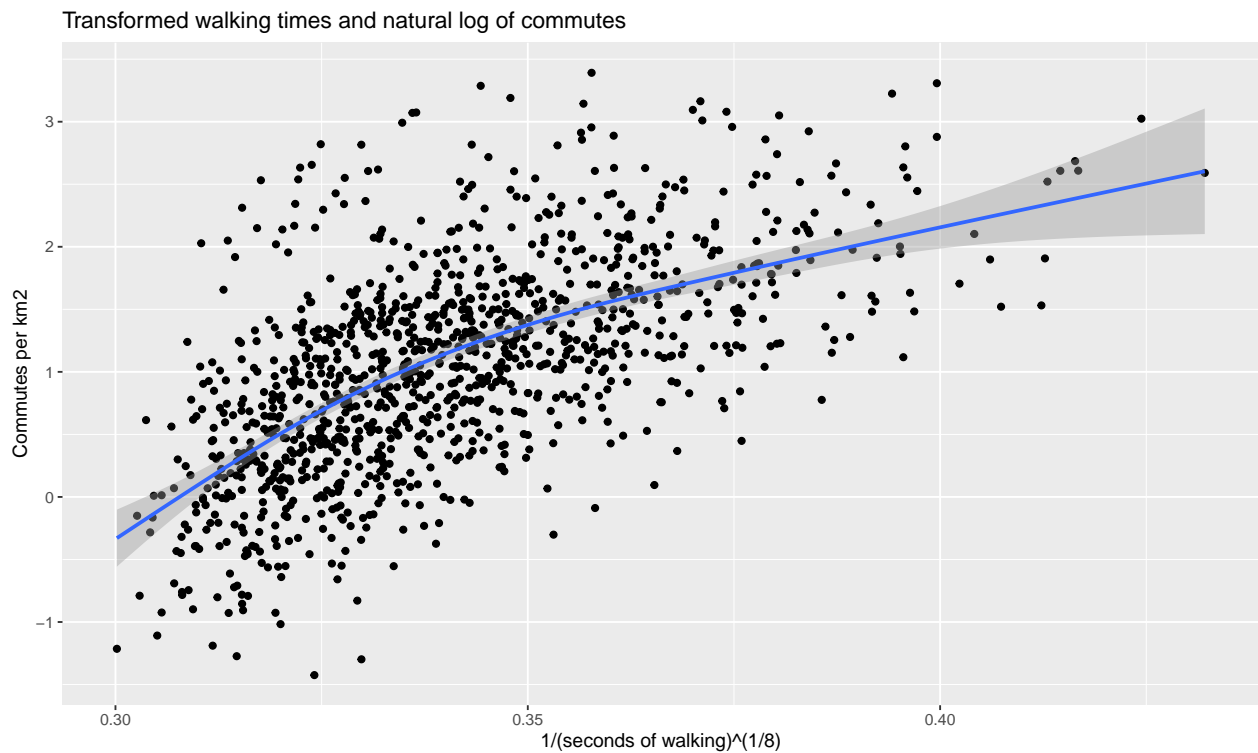

Figure 12: Time spent walking is transformed by raising it to the power of one-eighth and taking the inverse. Commute count is transformed with the natural log. The values are plotted against each other. A smoother line is overlaid in blue.

Figure 13: Diagnostic plots for the model of transformed walking time

Figure 14: Models for transportation modes. Each model is only plotted from their minimum to maximum observed travel time.

Figure 15: Models of transportation modes, zoomed on the range of 12min to 50mins. This range is seen in the travel time values for each transportation mode.

Figure 16: Global auto-correlation of job count using subway transit time for neighborhood weights

Figure 17: Global auto-correlation of job count using driving time for neighborhood weights

Figure 18: Global auto-correlation of job count using walking time for neighborhood weights

Figure 19: Global auto-correlation of job count using queens contiguity for neighborhood weights

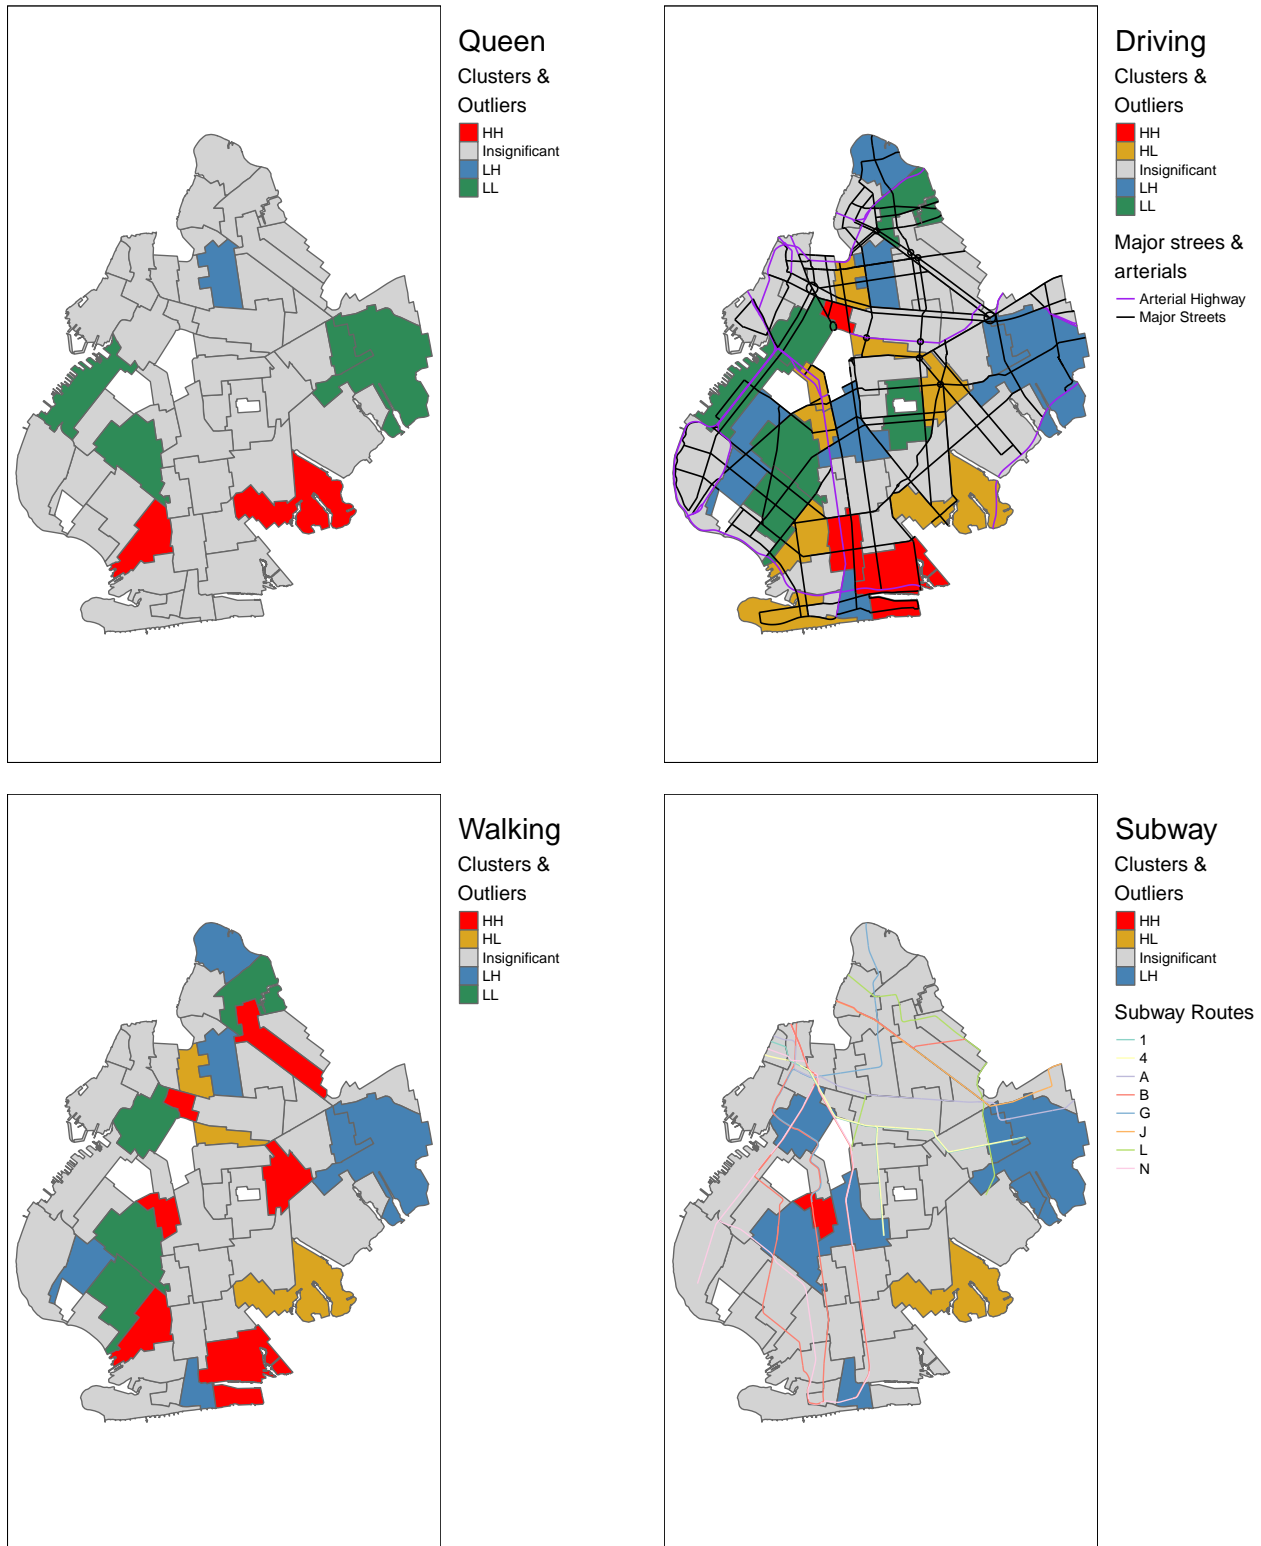

Figure 20: Local auto-correlation for job count of NTAs. Each map utilizes a unique neighborhood weighting. Top left uses queen contiguity. Top right uses driving time in traffic and is overlaid with major roads. Bottom left uses walking time. Bottom right uses transit time on the subway and is overlaid with the subway network.

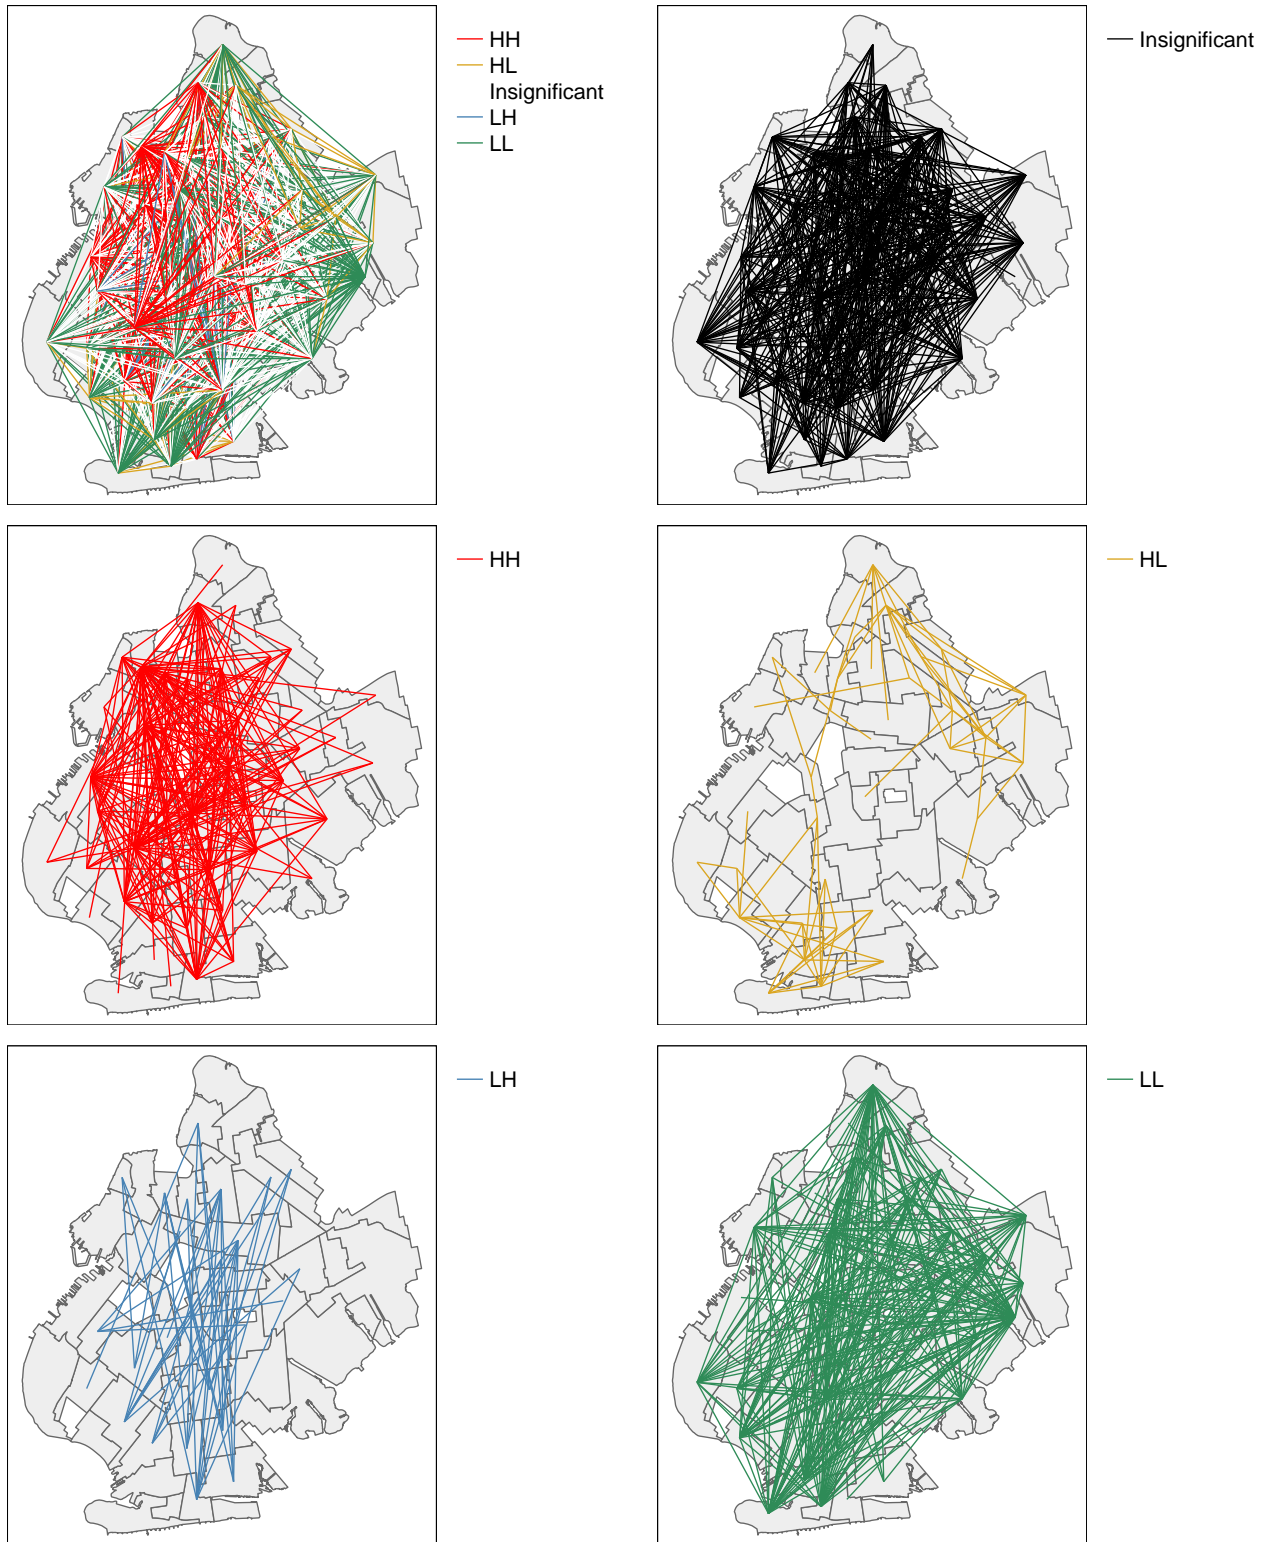

Figure 22: Local autocorrelation for commute network. Top left map shows all confidence types on one map. Top right shows Insignificant clusters. Middle left shows High High clusters. Middle right shows High Low clusters. Bottom left shows Low High clusters. Bottom right shows Low Low clusters

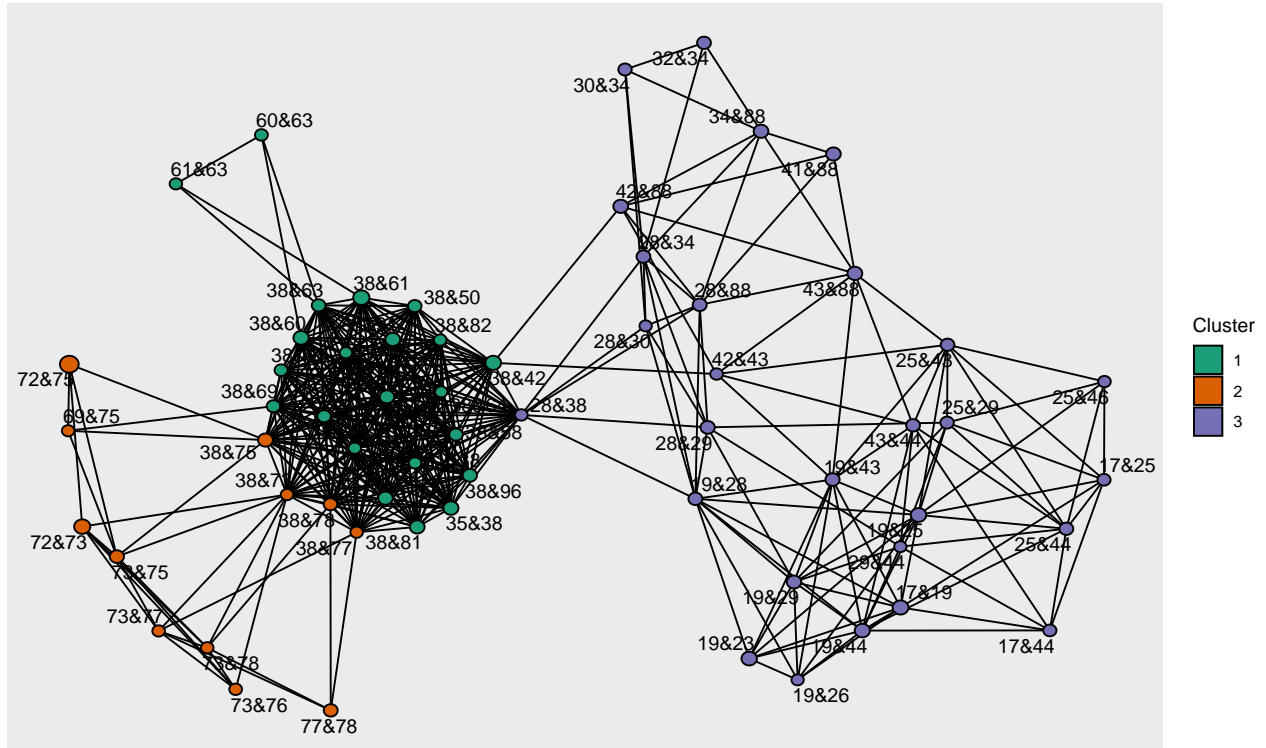

Figure 23: Graph of the top 5% most popular commutes through brooklyn and their interactions with each other. The color of the node reflects its membership in one of three clusters

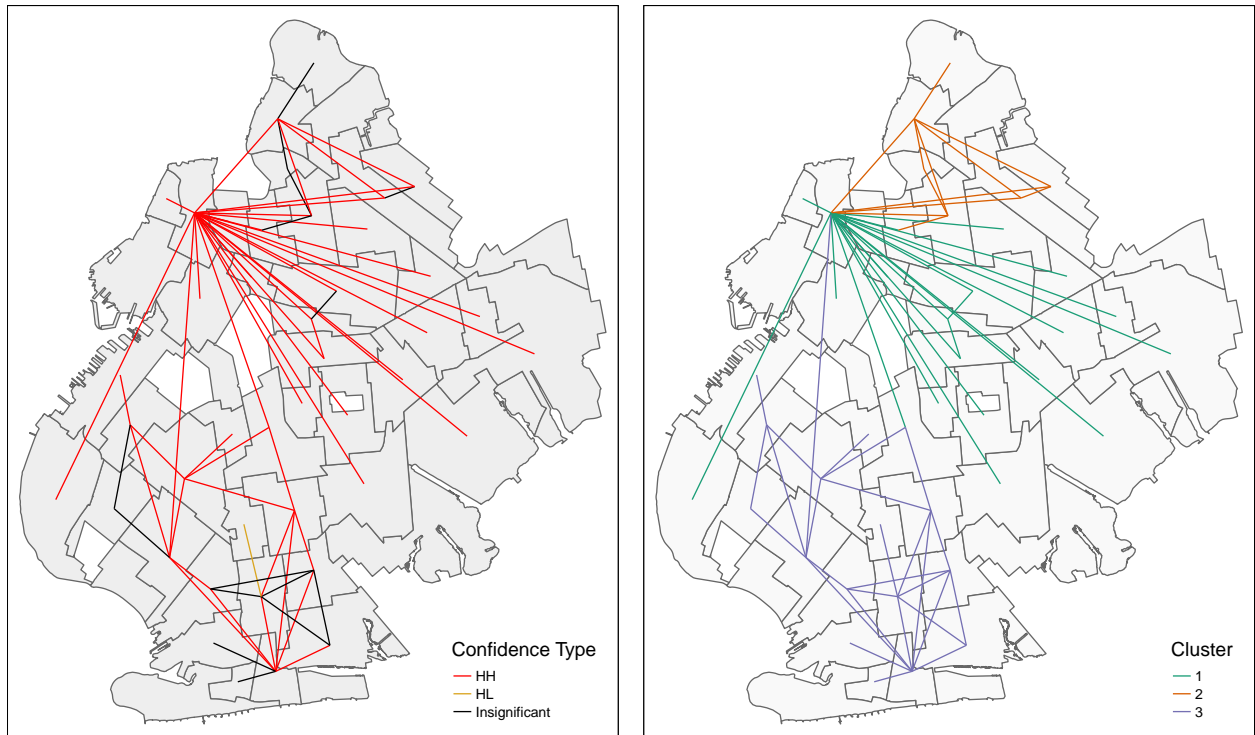

Figure 24: Geospatial distribution of the top 5% most popular commutes through brooklyn. Left diagram is the confidence type of the commute. Right diagram is commute's membership in the network cluster
